Eval Your AI Product in an Afternoon

A five-step check for designers. About two hours with 20 real answers from your product, and nothing beyond a spreadsheet.

01 Collect 20 real answers

Pull 20 real conversations or outputs from your product. Include the awkward ones: off-topic requests, missing data, things it should refuse.

From a real study: The study used 41 screenshots and deliberately included pricing, login and legal pages, where an AI audit has nothing to find.

02 Mark each one pass or fail

Ask one question: would I be happy if a real user got this? Write one plain line on the first thing wrong. No scores and no categories yet.

From a real study: Each of the 41 audits got one verdict and, when it failed, one line naming the first thing wrong.

03 Group the notes and count

Sort the notes into piles the way you would affinity-map research. Count each pile. The biggest one is your first problem.

From a real study: Six piles. The biggest was advice about things a single screenshot cannot show.

04 Write the biggest problem down as one rule

Make it a yes or no question that anyone on the team could apply to an answer and get the same verdict.

From a real study: The rule: every piece of advice is either seen (it points at something on the screen) or assumed. 93 of 116 pieces of advice were assumed.

05 Fix, then re-check the same 20 plus 5 new ones

Change one thing, rerun the same examples and apply the same rule. Add a few answers the fix never saw, so you know it works beyond the ones you tuned it on.

From a real study: Guessed advice fell from 80% to 68% on the tuned screens, but only from 92% to 88% on fresh ones.

#	Input (what the user asked or did)	Output (what the AI said)	Pass / Fail	First thing wrong (one line)	Group
